## 18 Weighted Bipartite Matching

#### Weighted Bipartite Matching/Assignment

- *►* Input: undirected, bipartite graph  $G = L \cup R$ , *E*.
- $\blacktriangleright$  an edge  $e = (\ell, r)$  has weight  $w_e \geq 0$
- $\blacktriangleright$  find a matching of maximum weight, where the weight of a matching is the sum of the weights of its edges

### Simplifying Assumptions (wlog [why?]):

- $\blacktriangleright$  assume that  $|L| = |R| = n$
- $\triangleright$  assume that there is an edge between every pair of nodes  $(\ell, r) \in V \times V$
- **▶ can assume goal is to construct maximum weight perfect** matching

# Weighted Bipartite Matching

#### Theorem 1 (Halls Theorem)

*A bipartite graph*  $G = (L \cup R, E)$  *has a perfect matching if and only if for all sets*  $S \subseteq L$ *,*  $|\Gamma(S)| \geq |S|$ *, where*  $\Gamma(S)$  *denotes the set of nodes in R that have a neighbour in S.*

18 Weighted Bipartite Matching

### Halls Theorem

#### Proof:

- $\Leftarrow$  Of course, the condition is necessary as otherwise not all nodes in *S* could be matched to different neigbhours.
- ⇒ For the other direction we need to argue that the minimum cut in the graph  $G'$  is at least  $|L|$ .
	- *<sup>ñ</sup>* Let *S* denote a minimum cut and let *L<sup>S</sup>* Ö *L* ∩ *S* and *R*<sup>*S*</sup>  $\triangleq$  *R* ∩ *S* denote the portion of *S* inside *L* and *R*, respectively.
	- $\triangleright$  Clearly, all neighbours of nodes in  $L_S$  have to be in *S*, as otherwise we would cut an edge of infinite capacity.
	- $\blacktriangleright$  This gives  $R_S \geq |\Gamma(L_S)|$ .
	- $\blacktriangleright$  The size of the cut is  $|L| |L_S| + |R_S|$ .
	- $\blacktriangleright$  Using the fact that  $|\Gamma(L_S)| \geq L_S$  gives that this is at least  $|L|$ .

### Algorithm Outline

### Idea:

We introduce a node weighting  $\vec{x}$ . Let for a node  $v \in V$ ,  $x_v \in \mathbb{R}$ denote the weight of node *v*.

**Follo** Suppose that the node weights dominate the edge-weights in the following sense:

```
x_u + x_v \geq w_e for every edge e = (u, v).
```
- $\blacktriangleright$  Let *H(* $\vec{x}$ *)* denote the subgraph of *G* that only contains edges that are tight w.r.t. the node weighting  $\vec{x}$ , i.e. edges  $e = (u, v)$  for which  $w_e = x_u + x_v$ .
- $\blacktriangleright$  Try to compute a perfect matching in the subgraph  $H(\vec{x})$ . If you are successful you found an optimal matching.

# Algorithm Outline

### What if you don't find a perfect matching?

Then, Halls theorem quarantees you that there is a set  $S \subseteq L$ , with  $|\Gamma(S)| < |S|$ , where  $\Gamma$  denotes the neighbourhood w.r.t. the subgraph  $H(\vec{x})$ .

Idea: reweight such that:

- ▶ the total weight assigned to nodes decreases
- $\rightarrow$  the weight function still dominates the edge-weights

If we can do this we have an algorithm that terminates with an optimal solution (we analyze the running time later).

# Algorithm Outline

### Reason:

*ñ* The weight of your matching *M*∗ is

$$
\sum_{(u,v)\in M^*} w_{(u,v)} = \sum_{(u,v)\in M^*} (x_u + x_v) = \sum_v x_v.
$$

 $\triangleright$  Any other perfect matching *M* (in *G*, not necessarily in  $H(\vec{x})$  has

$$
\sum_{(u,v)\in M} w_{(u,v)} \leq \sum_{(u,v)\in M} (x_u + x_v) = \sum_v x_v \enspace .
$$

# Changing Node Weights

Increase node-weights in  $\Gamma(S)$  by  $+\delta$ , and decrease the node-weights in *S* by −*δ*.

- ▶ Total node-weight decreases.
- *►* Only edges from *S* to  $R \Gamma(S)$ decrease in their weight.
- **Fince, none of these edges is** tight (otw. the edge would be contained in  $H(\vec{x})$ , and hence would go between *S* and Γ *(S)*) we can do this decrement for small enough *δ >* 0 until a new edge gets tight.

### Weighted Bipartite Matching

Edges not drawn have weight 0.

# Analysis

- $\triangleright$  We will show that after at most *n* reweighting steps the size of the maximum matching can be increased by finding an augmenting path.
- **Fig.** This gives a polynomial running time.

# Analysis

How many iterations do we need?

- **One reweighting step increases the number of edges out of** *S* by at least one.
- **Assume that we have a maximum matching that saturates** the set  $\Gamma(S)$ , in the sense that every node in  $\Gamma(S)$  is matched to a node in *S* (we will show that we can always find *S* and a matching such that this holds).
- **Fig. This matching is still contained in the new graph, because** all its edges either go between  $\Gamma(S)$  and *S* or between  $L-S$ and  $R - \Gamma(S)$ .
- **FI** Hence, reweighting does not decrease the size of a maximum matching in the tight sub-graph.

18 Weighted Bipartite Matching

# How to find an augmenting path?

#### Construct an alternating tree.

18 Weighted Bipartite Matching © Harald Räcke 529

### Analysis

#### How do we find *S*?

- ▶ Start on the left and compute an alternating tree, starting at any free node *u*.
- **Follo** If this construction stops, there is no perfect matching in the tight subgraph (because for a perfect matching we need to find an augmenting path starting at *u*).
- **►** The set of even vertices is on the left and the set of odd vertices is on the right and contains all neighbours of even nodes.
- **▶ All odd vertices are matched to even vertices. Furthermore,** the even vertices additionally contain the free vertex *u*. Hence,  $|V_{odd}| = |\Gamma(V_{even})|$  <  $|V_{even}|$ , and all odd vertices are saturated in the current matching.

## Analysis

- $\blacktriangleright$  The current matching does not have any edges from  $V_{\text{odd}}$  to  $L \setminus V_{\text{even}}$  (edges that may possibly be deleted by changing weights).
- **After changing weights, there is at least one more edge** connecting  $V_{\text{even}}$  to a node outside of  $V_{\text{odd}}$ . After at most *n* reweights we can do an augmentation.
- $\blacktriangleright$  A reweighting can be trivially performed in time  $\mathcal{O}(n^2)$ (keeping track of the tight edges).
- $\blacktriangleright$  An augmentation takes at most  $\mathcal{O}(n)$  time.
- $\blacktriangleright$  In total we obtain a running time of  $\mathcal{O}(n^4)$ .
- **A** more careful implementation of the algorithm obtains a running time of  $O(n^3)$ .
